ALBANY, N. Y.:

CHARLES VAN BENTHUYSEN & SONS.

1879.

PLATE I

PLATE I. (continued from page 10)

1900

Fig. 1. A view of the specimen showing the general shape and the position of the various parts.

Fig. 2. A view of the specimen showing the general shape and the position of the various parts.

Fig. 3. A view of the specimen showing the general shape and the position of the various parts.

Fig. 4. A view of the specimen showing the general shape and the position of the various parts.

Fig. 5. A view of the specimen showing the general shape and the position of the various parts.

Fig. 6. A view of the specimen showing the general shape and the position of the various parts.

Fig. 7. A view of the specimen showing the general shape and the position of the various parts.

1901

Fig. 8. A view of the specimen showing the general shape and the position of the various parts.

Fig. 9. A view of the specimen showing the general shape and the position of the various parts.

Fig. 10. A view of the specimen showing the general shape and the position of the various parts.

Fig. 11. A view of the specimen showing the general shape and the position of the various parts.

Fig. 12. A view of the specimen showing the general shape and the position of the various parts.

Fig. 13. A view of the specimen showing the general shape and the position of the various parts.

Fig. 14. A view of the specimen showing the general shape and the position of the various parts.

Fig. 15. A view of the specimen showing the general shape and the position of the various parts.

Fig. 16. A view of the specimen showing the general shape and the position of the various parts.

Fig. 17. A view of the specimen showing the general shape and the position of the various parts.

Fig. 18. A view of the specimen showing the general shape and the position of the various parts.

PLATE I.

PLATYCERAS (ORTHONYCHIA) SUBRECTUM.

Page 1.

Fig. 1. View of a small individual entirely destitute of shell.

Fig. 2. The concave or ventral side of a larger flat specimen, showing but little twisting except near the apex.

PLATYCERAS (ORTHONYCHIA) DENTALIUM.

Page 2.

Fig. 3. View of an imperfect specimen, showing the spiral form which has consisted of about one entire volution.

Figs. 4-6. Three views of a spirally compressed specimen, showing the minute incurved beak, and longitudinally rigid body, which is cancellated by transverse lines of growth.

Fig. 7. View of an elongate, imperfect specimen, mostly denuded of the shell, but showing the spiral character.

Fig. 8. A more rapidly expanding specimen, preserving the shell on the lower part and showing a deep revolving sulcus.

PLATYCERAS (ORTHONYCHIA) CONCAVUM.

Page 3.

Figs. 9, 10. Dorsal and ventral views of the type specimen, which is an internal cast, and imperfect at the apex, but shows the spiral form and the deep, somewhat undefined, broad sulcus of the ventral side. Williamsville, N. Y.

Figs. 11, 12. Views of the opposite sides of an individual which is imperfect at the apex, but retains the shell elsewhere, and shows the fine, even, lamellose concentric striae, crossed by a few faint longitudinal lines, and also the sulcus on the ventral side. Onondaga, N. Y.

PLATYCERAS (ORTHONYCHIA) CONICUM.

Page 3.

Figs. 13, 14. Lateral view and aperture of a broadly expanded specimen. The minute apex has been broken.

Figs. 15, 17. Lateral and upper views of a similar specimen, showing strong plications upon the margin.

Fig. 16. Lateral view of a flattened specimen of somewhat less expanded form.

This and the two preceding specimens are from the Upper Helderberg limestone at Onondaga, N. Y.

Fig. 18. View of a rapidly expanding specimen, with more attenuate apex. From the Hamilton group at Canandaigua Lake, N. Y.

Fig. 19. A small specimen, similar in form to the last, but having a small enrolled apex.

Figs. 20-22. Three views of an individual of highly conical form, with attenuated, subcentral apex, and strongly plicated margin. From the Hamilton group at Bellona, N. Y.

Fig. 23. Lateral view of a narrower conical form, strongly plicated at the margin, and imperfect at the apex. From the Hamilton group at Widder, C. W.

UPPER HELDERBERG & HAMILTON GROUPS.

(PLATYCERIDÆ.)

Palæontology N.Y. Vol. V.

Plate I.

PLATE II.

PLATYCERAS (ORTHONYCHIA) PERPLEXUM.

Page 4.

- Figs. 1, 2. Views of the opposite sides of a specimen, showing the form and the irregular plications.
Fig. 3. Lateral view of a compressed specimen, imperfect at the apex, showing the plicated surface and concentric striae.

PLATYCERAS ERECTUM.

Page 5.

- Fig. 4. View of the original specimen figured and described in the Fourth District Report. Upper Helderberg limestone, five miles east of Buffalo, N. Y.
Figs. 5, 6. Lateral and dorsal views of a specimen, showing a sudden expansion of the shell at the end of the first volution. From Cayuga, C. W.
Figs. 7, 8. Two views of a specimen, with less closely coiled beak. From the Hamilton group at Pavilion, N. Y.
Figs. 9, 10. Views of the opposite sides of a larger curved specimen. From the Hamilton group at Genesee, N. Y.
Fig. 11. Lateral view of a small specimen, with closely coiled apex. From the Hamilton group.

PLATYCERAS CARINATUM.

Page 5.

- Figs. 12, 13. Lateral and dorsal views of a small specimen. Upper Helderberg limestone, Helderberg mountains.
Figs. 14-16. Three views of a specimen. From near Williamsville, N. Y.
Figs. 17-19. A large internal cast, showing several plications on the right side. From the Upper Helderberg group, Sandusky, Ohio.
Figs. 20, 21. Two views of a specimen. From the Hamilton group at Canandaigua Lake, N. Y.
Figs. 22-25. Views of a very perfect specimen, from the same locality as the preceding.
Fig. 26. Posterior profile view of a large individual, showing an elevated obtuse carination along the back of the shell. From Bellona, N. Y.
Fig. 27. Lateral view of the same, showing plications on the left side, with the sinuosities and projections of the margin indicated by the direction of the surface striae.
Figs. 28, 29. Dorsal and lateral views of an internal cast, showing decided lobations on each side of the shell, and the carination in the center. Helderberg mountains, N. Y.

PLATYCERAS CONICUM.

Page 3.

- Figs. 30, 31. Lateral and upper views of an extremely carinate individual, with a regularly arcuate obtusely pointed apex. From Onondaga county, N. Y. (Reference to these figures is omitted in the text.)

PLATE III.

PLATYCERAS (ORTHONYCHIA) ATTENUATUM.

Page 6.

Fig. 1. Dorsal view of a small specimen which has been laterally compressed.

Figs. 2, 3. Dorsal and lateral views of a more expanded specimen, showing strong folds near the margin.

Fig. 4. Lateral view of the specimen fig. 1, showing the folds of the margin.

Figs. 5, 6. Lateral and dorsal views of an unusually expanded specimen, showing irregular pustulose ridges on the surface of the expanded portion.

PLATYCERAS BUCCULENTUM.

Page 10.

Fig. 7. Lateral view of a specimen which may be the young of *P. bucculentum*, but has the appearance of an adult shell. From Canandaigua Lake, N. Y.

PLATYCERAS AURICULATUM.

Page 7.

Figs. 8-10. Dorsal, right and left views of a specimen, showing the form of the shell and the lateral expansion, with its ridges. Darien, N. Y.

PLATYCERAS THETIS.

Page 8.

Figs. 11, 12. Left and right lateral views of a small specimen, showing the narrow form and enrolled beak.

Figs. 13, 14. Left and right lateral views of an unusually large specimen, showing a more strongly arcuate form.

Figs. 15, 16. Left views of two specimens of large size, showing some variation in form. From the Hamilton group at Canandaigua Lake and Bellona, N. Y.

PLATYCERAS SYMMETRICUM.

Page 9.

Fig. 17. Lateral view of a large specimen, referred with some doubt to this species. From the Hamilton group, Canandaigua Lake, N. Y.

Figs. 18-21. Four views of one of the typical specimens exhibiting the general features of the species. Fig. 20 shows the symmetrically coiled beak. Fig. 21 is accidentally compressed on one side. From Canandaigua Lake, N. Y.

Figs. 22-24. Three views of a specimen, showing a loosely coiled beak (except at the apex) and strongly plicated margin.

Fig. 25. Dorsal view of a specimen, showing a strong anterior fold. From Canandaigua Lake, N. Y.

PLATYCERAS BUCCULENTUM.

Page 10.

Fig. 26. Lateral view of a specimen, showing the folds of the shell on the left side.

Fig. 27. Dorsal view of an individual, showing the strong lateral folds.

Fig. 28. Dorsal view of the specimen fig. 26.

Fig. 29. The aperture of a large symmetrical specimen, showing a fold in the posterior margin. Livingston county and at Canandaigua Lake, N. Y.

PLATYCERAS THETIS? var. SUBSPINOSUM.

Page 9.

Fig. 30. View of a large flattened specimen, possessing many of the features of *P. Thetis*, but more robust and with the aperture contracted on the right side and strongly plicated. There are a few short spines at the summit of the volution. From the Hamilton group at Canandaigua Lake, N. Y.

HAMILTON GROUP.

(PLATY CERIDÆ .)

Palæontology NY Vol.V.

Plate III.

PLATE V.

PLATYCERAS ECHINATUM.

Page 13.

Figs. 1, 2. Dorsal and lateral views of a small specimen, enlarged to twice the natural size, showing the characters of surface when exfoliated, leaving only the spine-bases remaining. From the Hamilton group at Ludlowville, Cayuga Lake, N. Y.

Figs. 3, 4. Dorsal and lateral views, natural size, of a specimen denuded of the exterior shell and showing the bases of the spines as tubercles. From the Tully limestone at Ovid, N. Y.

PLATYCERAS DUMOSUM var. RARISPINUM.

Page 16.

Fig. 5. Lateral view of a small specimen, showing a few scattered spines. Oneida county, N. Y.

Figs. 6, 7. Lateral and dorsal views of a larger specimen, similar in character to the preceding. Darien, N. Y.

Fig. 10. Oblique side view of a specimen which is partly imbedded in rock, and preserves several of the spines in place. Schoharie, N. Y.

PLATYCERAS FORNICATUM var. CONTRACTUM.

Page 12.

Figs. 8, 9. Two views of the specimen referred to as a variety in the original description of *P. fornicatum*.

PLATYCERAS DUMOSUM, Conrad.

Page 14.

Fig. 11. View of a small specimen preserving several spines and spine-bases. Falls of the Ohio.

Fig. 12. View of a larger and more robust specimen, partially imbedded in the rock, and showing numerous spine-bases. Schoharie, N. Y.

Fig. 13. View of a specimen with a large number of broken and displaced spines. From the Corniferous limestone near Columbus, Ohio.

Figs. 14, 15. Two views of a large ventricose individual (the type specimen used by Mr. Conrad for description), showing the bases of hollow spines, covering almost the entire surface. Schoharie, N. Y.

Fig. 16. The aperture of a long slender specimen, similar to figs. 11 and 12. The surface shows numerous spine-bases, and a plicated margin. Helderberg mountains, N. Y.

UPPER HELDERBERG GROUP.

(PLATYCERIDÆ.)

Palæontology NY Vol V Pt II

Plate V.

PLATE VI.

PLATYCERAS DUMOSUM, *Conrad*.

Page 14.

Fig. 1. View of a large ventricose specimen imbedded in rock, showing the form of the aperture and the long submarginal spines in place. Schoharie, N. Y.

PLATYCERAS MULTISPINOSUM, *Meek*.

Page 15.

Figs. 2, 3. Ventral and lateral views of a specimen communicated by Dr. J. S. Newberry for comparison with *P. dumosum*.

UPPER HELDERBERG GROUP.

Palæontology NY. Vol. IV. Pt. II

Plate VI.

FIG. 1.

Tridacna (large).

FIG. 2.

FIG. 3. *Tridacna* (large). The same as FIG. 1, but the growth lines are more distinct, and the shape is more rounded.

FIG. 4.

Tridacna (large).

FIG. 5.

FIG. 6. *Tridacna* (large). The same as FIG. 1, but the growth lines are more distinct, and the shape is more rounded.

FIG. 7.

Strophodonta (small).

FIG. 8. *Strophodonta* (small). The same as FIG. 7, but the growth lines are more distinct, and the shape is more rounded.

PLATE VII.

PLATYCERAS UNDATUM.

Page 17.

Figs. 1, 2. Views of the opposite sides of an internal cast, showing transverse lines of broad tubercles, and giving the general form of the shell. The original shell has doubtless been marked by strong spines.

PLATYCERAS DUMOSUM, *Conrad*.

Page 14.

Fig. 3. Dorsal view of the specimen represented on Plate V, fig. 16.

PLATYCERAS NODOSUM.

Page 17.

Figs. 4, 5. Lateral and dorsal views of an internal cast, showing very strong tubercles, indicating spine-bases in a somewhat quincunx arrangement.

PLATYCERAS CRASSUM.

Page 18.

Fig. 6. View of an internal cast which is probably of this species. Schoharie, N. Y.

Fig. 7. A somewhat smaller individual which is more expanded toward the aperture, partially from compression. Clarksville, Albany county, N. Y.

Figs. 8-10. Three views of the typical specimen which is a partial cast and shows great thickness of shell. Helderberg mountains, N. Y.

UPPER HELDERBERG GROUP.

(PLATYCERIDÆ.)

Palæontology NY. Vol. V. Pt. II.

Plate VI.

PLATE I

PLATE VIII.

PLATYCERAS ARGO.

Page 19.

- Figs. 1-3. Three views of the originally described specimen; a partial internal cast, retaining the impressions of the concentric undulations of the surface.
- Fig. 4. View of the right side of a specimen, partially exfoliated. Along the middle can be traced the remains of a deep notch which existed in the lip, now forming an elevated ridge somewhat obscured by adhering rock.
- Fig. 5. View of the opposite side of the specimen represented in fig. 4.
- Fig. 6. Ventral view of the same, showing the depth of the shell, and the sinistrally coiled volutions.

PLATYCERAS AMMON.

Page 20.

- Fig. 7. View of an individual of medium size, showing the strong volutions and the peculiar lamellose structure. Port Colborne, Canada.
- Figs. 8, 9. Views of the opposite sides of a large individual, showing the general form of the shell. Darien, N. Y.
- Fig. 10. Ventral view of the specimen figs. 8 and 9, showing the enrolling of the beak which in the figure is represented as too nearly on the same plane; it is directed more upwards, leaving a greater depth of the outer volution on the lower side.

UPPER HELDERBERG GROUP.

SECTION 5. *General Statement of the Lands Belonging to the State.*

PLATE IX.

PLATYOSTOMA TURBINATA var. COCHLEATA.

Page 28.

- Figs. 1, 2. The opposite sides of an irregularly coiled specimen, showing a moderately elevated spire.
Fig. 3. The aperture of an individual, with more elevated spire and narrower form. The lower side of the last volution shows a depressed line marking the position of a notch in the outer lip. The specimen is slightly umbilicate.
Fig. 4. Enlargement of the striæ where crossing the line of the notch in the outer volution.
Fig. 5. Apertural view of a specimen having a line indicating a notch in a higher position on the volution than the preceding, only visible on the outer volution and obsolete at the lip. The inner lip of the aperture is disunited from the columella.
Fig. 6. An individual with the outer volution disunited and much contracted near the aperture.
Fig. 7. Dorsal view of the same specimen.
Fig. 8. A larger individual, showing a double sinuosity in the outer lip.
Figs. 9-11. A still larger specimen, having an indistinct band bordering the suture.

PLATYOSTOMA TURBINATA.

Page 27.

- Figs. 12, 13. Two views of a young individual with a nearly flattened spire.
Figs. 14, 15. A larger specimen of similar character, with a depressed spire and a broad, shallow sinuosity in the lip.
Figs. 16, 17. Two views of a still larger specimen, with the spires somewhat depressed below the outer volution, and the depression bordered in part by a sulcated band, indicating a slit in the aperture at that stage of growth.
Figs. 18, 19. A similar specimen accidentally compressed and shortened, and showing the center of the sinuosity marked by a projecting point on the lip.
Figs. 20, 21. Two views of the specimen from which the species was originally described.
Fig. 22. An apertural view of a specimen differing somewhat in the form of the columella and aperture and also in the height of the spire.
Figs. 23, 24. A large individual, ridged and plicated on the outer volution.

PLATYOSTOMA UNISULCATA.

Page 26.

- Figs. 25, 26. Two views of the original specimen, from which Mr. Conrad's description was taken.

PLATYOSTOMA TURBINATA var.

Page 29.

- Fig. 27. The aperture of a young individual bearing considerable resemblance to *P. turbinata* var. *cochleata*.
Figs. 28-30. A characteristic full-grown specimen of this variety.

PLATYOSTOMA PLEUROTOMA.

Page 30.

- Figs. 31-33. Three views of a specimen of this species.
Fig. 34. The aperture of a large individual, showing the twisting of the columella and the form of the shell.
Fig. 35. Partial side view, showing more distinctly the twisting of the columellar lip.*

* The columellar lip in these individuals resembles that of *Strophostylus*, while the surface characters and form of volution are clearly characteristic of *Platyostoma*.

UPPER HOLOCENE & HAMILTON GROUPS.

(JANTHINIDAE)

Palæontology of NY Vol VP:II

Plate V

PLATE X.

PLATYOSTOMA LINEATA.

Page 21.

- Fig. 1. A small patulose specimen. From the Upper Helderberg group, Onondaga county.
- Fig. 2. The aperture and spire of a symmetrical specimen, having the normal characters of the species.
- Figs. 3, 4. Summit of the spire and lateral view of the specimen fig. 2.
- Figs. 5, 6. The spire and aperture of a larger specimen, differing from the preceding in the curving of the columella.
- Fig. 7. The spire of a specimen of medium size, which, during a part of its growth, has possessed a slit in the outer lip, occurring, apparently, from some accidental cause, at the commencement of the outer volution, and afterwards becoming closed, has left the surface plicated and irregular. Upper Helderberg group, Schoharie, N. Y.
- Fig. 8. The spire of a large individual of the ordinary form of the species, as it occurs in the limestone.
- Fig. 9. A similar view of a more robust individual.
- Fig. 10. Lateral view of the outer volution of a specimen similar to figure 9.
These specimens, with two exceptions, are from the Upper Helderberg limestone at Williams-ville, N. Y.; they preserve, in a well-marked manner, the concentric and radiating striæ.
- Fig. 11. The spire of a specimen somewhat similar to fig. 7.
- Fig. 12. Enlargement of the surface striæ of the same. Hamilton shales, near Geneseo, N. Y.
- Figs. 13, 14. Two views of a specimen, preserving the surface in great perfection. The specimen is slightly depressed from accidental causes. From the Hamilton shales, Canandaigua Lake.
- Fig. 15. Enlargement of the surface of the preceding.
- Figs. 16-18. Three views of a large specimen, preserving the form of the aperture and peristome. The aperture is slightly rhomboidal, varying somewhat from the prevailing type. From the Hamilton shales at Canandaigua Lake.
- Fig. 19. An unusually large individual, which preserves the striæ of growth very distinctly, while the concentric striæ are obsolete. Corniferous limestone, Darien, N. Y.
- Figs. 20, 21. Two views of an internal cast of the same species. Chemung group.

PLATYOSTOMA LINEATA var. CALLOSA.

Page 23.

- Fig. 22. The aperture of a specimen which has the appearance of *P. lineata*, but with a thickened callus on the inner lip.
- Fig. 23. The spire of the same specimen.

PLATYOSTOMA DEFIGURATA.

Page 24.

- Fig. 24. The apertural side of the specimen of which the outer volution has been crushed.

PLATYOSTOMA LINEATA var. AMPLA.

Page 23.

- Fig. 25. The spire.
- Fig. 26. The apertural side, showing the great elevation, large aperture and peculiarity of the columella, approaching in character to *Strophostylus*.

PLATYOSTOMA EUOMPHALOIDES.

Page 25.

- Fig. 27. Dorsal view of the specimen. Hamilton group, York, Livingston county, N. Y.
- Fig. 28. The base of the specimen, showing the aperture and the columellar lip modified by the preceding volution.
- Fig. 29. The spire as seen from above, showing the depressed upper surface of the outer volution.

UPPER Helderberg & Hamilton Groups.

(JANTHINIDÆ)

Palæontology of N.Y. Vol. V. Pt. II.

Plate X.

PLATE XI.

PLATYOSTOMA UNISULCATA var.

Page 27.

- Fig. 1. Apertural view, showing the general form and elevation of the shell, the columella, etc.
Fig. 2. The back of the same specimen, showing the angularity of the volution.
Fig. 3. The spire.

PLATYOSTOMA LINEATA, var. SINUOSA.

Page 24.

- Fig. 4. Front view of a small specimen with a depressed spire.
Fig. 5. Basal view, showing the deep sinus in the aperture. Hamilton group, Livingston county, N. Y.
Figs. 6, 7. Apertural view and spire of a larger specimen, with much higher spire and rounded volutions.
From the Hamilton group, Canandaigua Lake, N. Y.
Fig. 8. Basal view of the same, showing the deep sinus of the lip.

PLATYOSTOMA APLATA.

Page 26.

- Fig. 9. The spire of an imperfect specimen. From the Schoharie grit, Schoharie, N. Y.

PLEUROTOMARIA? sp.?

Naticopsis? cretacea, HALL. Illustrations of Devonian Fossils: Gasteropoda, pl. 11. 1876.

Not *Naticopsis cretacea*, H. & W. Twenty-third Rep. N. Y. State Mus. Nat Hist., p. 240. 1873.

Not *Naticopsis laevis*, MEEK. H. & W. Ib. Explanation pl. 12, figs. 3-5.

- Fig. 10. The spire of an imperfect cast referred with doubt to this species.
Fig. 11. Front view of the same, showing the obliquity of the shell and the substance of the callus filling the umbilicus. Upper Helderberg limestone near Clarence Hollow, N. Y.
Figs. 12, 13. Two views of an internal cast. Upper Helderberg limestone near Columbus, Ohio.

STROPHOSTYLUS UNICUS.

Page 30.

- Fig. 14. Front view of the typical specimen, showing the columella and the form of the shell.
Fig. 15. Summit view of the same specimen. From the Schoharie grit, Schoharie, N. Y.

STROPHOSTYLUS VARIANS.

Page 31.

- Figs. 16, 17. Two views of a young, very oblique specimen, showing, in fig. 16, the peristome nearly detached from the body of the preceding volution—an exceptional feature.
Fig. 18. Enlargement of the surface striæ from a small, well-preserved specimen.
Figs. 19, 20. Two views of a larger specimen, showing the peristome more completely united to the preceding volution.
Fig. 21. A medium-sized specimen, showing very great obliquity of the last volution and a slight separation of the peristome from the body-whorl.
Figs. 22-24. Other examples, showing the form of the shell and the very broad umbilicus.
Fig. 25. A small specimen, showing strong plications near the aperture, indicating the existence of a notch in the peristome during the later period of its growth.
Fig. 26. A large and more rotund specimen, showing an injury to the peristome during growth.
Figs. 27, 28. Two views of a large, well-formed, rotund specimen. The second figure shows the obliquity of the outer lip to the axis of the shell.
Figs. 29, 30. Two views of a large specimen, the latter showing the inner lip spreading over the preceding volution.
Fig. 31. A large oblique specimen with the peristome much thickened.
The specimens are all from the Upper Helderberg limestone, Onondaga county, N. Y.

UPPER HELDERBERG GROUP.

UPPER HELDERBERG & HAMILTON GROUPS.

(PYRAMIDELLIDÆ.)

Palæontology NY Vol. IV. Pt. II.

Plate XIII.

PLATE XIII.—*Continued.*

LOXONEMA HAMILTONIÆ.

Page 45.

Fig. 15. A specimen of the usual size, showing the characteristic features of the species.

Fig. 17. An individual of similar character, scarcely differing in size, and preserving one volution less than the preceding.

LOXONEMA PEXATA.

Page 42.

Fig. 16. A typical specimen of the species. Dublin, Ohio.

Fig. 18. A larger individual, showing the aperture in part. From the same locality as the preceding.

LOXONEMA DELPHICOLA.

Page 47.

Figs. 19, 20. Two small specimens, showing considerable variation in the apical angle, but both having the sutural band. From the Hamilton group; the first specimen from Cayuga, the other from Seneca Lake, N. Y.

Fig. 21. A specimen, showing very coarse markings and a well-defined sutural band. From the soft shales of the Hamilton group, Cayuga Lake, N. Y.

Figs. 22, 23. Two views of a specimen, with finer surface-markings and a very distinct sutural band. From the harder layers of the Hamilton group, Delhi, N. Y.

Fig. 24. A specimen enclosed in a coating of smoothed and polished shale (slickensides)—a very common condition of the species in the soft shales. From near Geneva, N. Y.

Fig. 25. A similarly coated specimen, from Cayuga Lake, N. Y. These specimens indicate the commencement of the accretion of soft material about the shell, which, in its final condition, envelops the fossil in a more or less distinctly formed concretion.

PLATE XIV.

LOXONEMA DELPHICOLA.

Page 47.

Fig. 1. A large compressed specimen, marked by fine striae, and showing a distinct sutural band. Hamilton shales, near Bellona, N. Y.

Fig. 2. A specimen from the same locality having the last volution greatly expanded, with fine markings, while the upper part is more coarsely marked. The sutural band is unusually wide. The apparent distortion is mainly a condition of growth, and not accidental.

It may be questionable whether the existence of a sutural band is of specific importance, and the degree of development of this feature in different individuals suggests a doubt as to the reliance of this character for specific distinction between *L. Hamiltonæ* and *L. delphicola*.

LOXONEMA BELLONA.

Page 46.

Fig. 3. A specimen which is mostly denuded of the shell, but showing the form of the volutions. A small fragment of shell on the body-volution exhibits the surface-marking as indicated in the figure.

Figs. 4, 5. Two fragments showing the form of volution and surface-markings.

LOXONEMA TEREBRA.

STATE TAX

AN ACT TO

IMPOSE

ON THE

PROPERTY OF THE STATE OF NEW YORK, AND TO PROVIDE FOR THE COLLECTION OF THE SAME.

SECTION 1.

There shall be levied and collected on the property of the State of New York, an annual tax of one per centum on the value of the same, to be paid in advance of the first day of January next following the assessment thereof.

The tax shall be levied and collected on the property of the State of New York, in the same manner and to the same effect as the tax on the property of the State of New York, as provided in the act to amend the act in relation to the tax on the property of the State of New York, passed at the session of the Legislature at Albany, in the year one thousand eight hundred and eighty-two.

SECTION 2.

The tax shall be levied and collected on the property of the State of New York, in the same manner and to the same effect as the tax on the property of the State of New York, as provided in the act to amend the act in relation to the tax on the property of the State of New York, passed at the session of the Legislature at Albany, in the year one thousand eight hundred and eighty-two.

SECTION 3.

The tax shall be levied and collected on the property of the State of New York, in the same manner and to the same effect as the tax on the property of the State of New York, as provided in the act to amend the act in relation to the tax on the property of the State of New York, passed at the session of the Legislature at Albany, in the year one thousand eight hundred and eighty-two.

SECTION 4.

The tax shall be levied and collected on the property of the State of New York, in the same manner and to the same effect as the tax on the property of the State of New York, as provided in the act to amend the act in relation to the tax on the property of the State of New York, passed at the session of the Legislature at Albany, in the year one thousand eight hundred and eighty-two.

SECTION 5.

The tax shall be levied and collected on the property of the State of New York, in the same manner and to the same effect as the tax on the property of the State of New York, as provided in the act to amend the act in relation to the tax on the property of the State of New York, passed at the session of the Legislature at Albany, in the year one thousand eight hundred and eighty-two.

SECTION 6.

The tax shall be levied and collected on the property of the State of New York, in the same manner and to the same effect as the tax on the property of the State of New York, as provided in the act to amend the act in relation to the tax on the property of the State of New York, passed at the session of the Legislature at Albany, in the year one thousand eight hundred and eighty-two.

SECTION 7.

The tax shall be levied and collected on the property of the State of New York, in the same manner and to the same effect as the tax on the property of the State of New York, as provided in the act to amend the act in relation to the tax on the property of the State of New York, passed at the session of the Legislature at Albany, in the year one thousand eight hundred and eighty-two.

- Fig. 25. A dorsal view of a specimen in which the shell is partially preserved.

PORCELLIA NAIS.

Page 127.

- Fig. 26. A dorsal view of the specimen, showing the mesial band.
Fig. 27. An oblique ventral view of the preceding specimen.
Fig. 28. The inner volutions of another individual, showing the fine cancellating striae and lateral nodes.

PLATE XXVII.

EUOMPHALUS (PLEURONOTUS) DECEWI.

Pages 55 and 137.

- Fig. 1. A lateral view into the spiral depression, exhibiting the angular form of the aperture, as shown where the shell lies upon its base.
- Fig. 2. The umbilical side of the specimen, showing the subquadrate form of the aperture as seen from beneath. The shell becomes thickened and lamellose towards the mouth. The surface-markings are only partially preserved on a part of the outer volution—the remaining portion of the shell having been covered by a *Stromatopora*.
- Fig. 3. The upper side of the shell, showing the depressed spire. The surface-markings are in part preserved, while much of the anterior portion of the last volution is covered by a Bryozoan. The peripheral band is distinctly marked, even where the shell is removed, and the depth of the marginal sinus is shown by the direction of the striæ—the aperture being filled with *Stromatopora*.
- Fig. 4. A section across the centre, as illustrated on plate 15; the upper part of the figure, *a*, cutting the volution (of a cast) near the aperture; *b* showing the form at half a volution preceding; and *c*, the form at a single volution from the aperture.

EUOMPHALUS (STRAPAROLLUS) CLYMENIOIDES.

Page 62.

- Fig. 5. The upper side of a large specimen, preserving a little more than one volution entire, with the remaining portion crushed and imperfect.
- Fig. 6. A smaller specimen, showing a single volution with partial impressions of the remaining volutions. Both the specimens are casts of the interior.

EUOMPHALUS (STRAPAROLLUS) HECALE var. CORPULENS.

See page 59.

PLEUROTOMARIA ADJUTOR.

Page 80.

Fig. 1. A figure of the peripheral band, and the striae above and below, enlarged three diameters.

PLEUROTOMARIA ITYS.

Page 76.

Fig. 2. A figure of the peripheral band, and the striae above and below, enlarged three diameters.

PLEUROTOMARIA INSOLITA.

Page 81.

Fig. 3. The mesial band and adjacent striae, enlarged five diameters.

PLEUROTOMARIA NITELLA.

Page 85.

Fig. 4. An enlargement of the mesial band, showing the bicarination on each side, with the simple sharp striae; four diameters.

PLEUROTOMARIA ITYS var. TENUISPIRA.

Page 87.

Fig. 5. The peripheral band, with the adjacent striae, enlarged four diameters.

PLEUROTOMARIA CAPILLARIA, var.

Page 87.

Fig. 6. An enlargement of the peripheral band, showing a single revolving line and more distant striae than the typical forms of the species. See figures 20 and 21.

PLEUROTOMARIA CAPILLARIA.

See page 87.

Fig. 7. An enlargement from the ordinary form of this species, showing a striate peripheral band, and closely arranged striae above and below.

PLEUROTOMARIA SULCOMARGINATA.

Page 69.

Fig. 8. An enlargement showing a plain peripheral band with the striae carinated above and below; two diameters.

Fig. 9. A similar enlargement from another specimen, showing a striated peripheral band, with the striae uninterrupted above and marked by a very faint carination below; three diameters.

PLEUROTOMARIA LUCINA.

Page 67.

Fig. 10. The surface of a specimen from the Hamilton group, showing the character of the striae on the two outer volutions—the peripheral band on the last one being marked by fine transverse striae, while the one preceding it has both transverse and revolving striae; natural size.

Fig. 11. The surface of a specimen from the Upper Helderberg limestone, showing the character of the peripheral band, with the strongly cancellated striae above and below; enlarged two diameters.

PLEUROTOMARIA QUADRILIX.

Page 86.

Fig. 12. An enlargement of the peripheral band and surface striae; two diameters.

PLEUROTOMARIA TRILIX.

Page 79.

Fig. 13. An enlargement of the peripheral band and adjacent striae, giving the characteristics of the surface; three diameters.

TROCHUS (PALÆOTROCHUS) KEARNEYI.

Page 133.

Fig. 14. The dorsal side of a specimen which preserves the striae upon the last volution; the upper volutions being denuded of the shell, and the apex incomplete.

UPPER HELDERSBERG & HAMILTON GROUPS.

(PLEUROTOMARIIDÆ .)

Palæontology of NY Vol. V. Pt. II.

Plate XXX.

PLATE XXX—*Continued.*

PLEUROTOMARIA FILITEXTA.

Page 73.

Fig. 15. The upper side of a small individual.

Fig. 16. A large individual which is vertically compressed and somewhat distorted.

Fig. 17. A large specimen, imperfect in the spire, which has been laterally compressed, giving an exaggerated elevation to the volutions. These last two figures are from unusually large individuals of the species.

PLEUROTOMARIA QUADRILIX.

Page 86.

Fig. 18. A lateral view, showing the form of the shell and the character of the peripheral band. The last volution is incomplete. Enlarged to three diameters.

PLEUROTOMARIA NITELLA.

Page 85.

Fig. 19. A lateral view showing the form of the spire, the character of the peripheral band and striae (which are farther enlarged in fig. 4), enlarged two diameters.

PLEUROTOMARIA CAPILLARIA, var. RUSTICA, n. var.

Page 87.

Fig. 20. The upper side of an imperfect specimen, showing the great expansion of the outer volution.

Fig. 21. A lateral view of a similar form, which shows a much less elevation of the spire than the ordinary forms of the species.

Fig. 22. A very large and much expanded specimen, which is apparently only an exaggerated form of this variety.

These all differ from the typical forms of *P. capillaria* in the comparatively less elevated spire and greater expansion of the outer volution.

PLEUROTOMARIA LUCINA.

Page 67.

Fig. 23. The outer volution, showing the spiral band without defined limitation, and near the aperture the mark of a fracture during the life of the animal, followed by some irregularity in the subsequent mode of growth.

PLEUROTOMARIA LUCINA?

See page 67.

Fig. 24. A specimen of irregular form and growth, which has the aspect of a dwarfed and exaggerated variety of *P. arata* or *P. Lucina*, preserving some features of both. The striae, so far as preserved, have the character of the latter species, while the costae present much similarity to the former.

PLEUROTOMARIA ITYS, var. TENUISPIRA.

Page 87.

Fig. 25. The posterior side of the specimen, showing the form of the aperture and rapidly attenuating spire, enlarged two diameters. See, also, figure 5.

PLEUROTOMARIA ARATA.

Page 64.

Fig. 26. A very rotund form of this species. The specimen is a cast of the interior, preserving the remains of the concentric costae upon the upper side of the last volution.

Fig. 27. The upper side of an extremely depressed specimen, partially preserving the shell in a macerated condition, and showing the strong concentric costae.

MURCHISONIA MICULA.

Page 93.

Fig. 28. An enlargement of the last volution, showing the peripheral band, with the impressed line below, and also the subcarinate feature of the upper margin of the volution.

MURCHISONIA INTERCEDENS.

Page 92.

Fig. 29. The posterior side, showing the subcentral peripheral band and nearly entire aperture; natural size.

PLATE XXXI.

TENTACULITES ARENOSUS.

Page 166.

Fig. 1. An internal cast.

Fig. 2. Enlargement of the same. The lower end shows a fragment of the shell and its relative thickness.

TENTACULITES SCALARIFORMIS.

Page 167.

Fig. 3. A specimen from cherty limestone of the Upper Helderberg group.

Fig. 4. Enlargement of the same, showing the form of the annulations; the surface has obscure encircling striae not well indicated on the figure.

Fig. 5. A specimen which retains the shell.

Fig. 6. Enlargement of the same, showing the annulations and the encircling striae.

Fig. 7. A specimen of somewhat different form.

Fig. 8. Enlargement of the same.

Fig. 9. A farther enlargement, showing the irregularity of the striae and their existence on the annulations and in the depressions between.

Fig. 10. Enlargement of a specimen which shows an inequality in the strength and distance of the annulations.

Fig. 11. Enlargement of a specimen in more compact limestone, having the shell removed by the fracture of the rock, and showing its thickness.

TENTACULITES GRACILISTRIATUS.

Page 173.

Figs. 12-14. Enlargement (to eight diameters) of three specimens, showing the difference in form and surface characters. See plate 31 A.

TENTACULITES BELLULUS.

Page 169.

Fig. 15. A specimen showing the general features of the species.

Fig. 16. Enlargement of the same, showing the form of the annulations and the encircling striae.

Fig. 17. Enlargement of a specimen showing similar features. The shell is broken at a point near the middle, showing its thickness.

Fig. 18. A further enlargement of the upper portion, showing the more abrupt slope of the annulations on the apical side (lower side of figure).

TENTACULITES ATTENUATUS.

Page 170.

Fig. 19. A gutta-percha impression from a fragment of the rock, showing a group of the shells.

Fig. 20. An enlargement of one of the individuals from the same piece of rock.

TENTACULITES SPICULUS.

Plate XXXI

PLATE XXXI A.

STYLIOLA FISSURELLA.

Page 178.

- Fig. 1. A fragment of slate with numerous crushed specimens of the fossil, enlarged to three diameters.
- Figs. 2-6. Individuals from the surface of the slate, showing the variety of form and surface-markings; fig. 2 being strongly striate longitudinally; fig. 3 showing transverse and longitudinal striae; and fig. 4 preserving only transverse striae; while figs. 5 and 6 are without visible striae under an ordinary lens. All the preceding figures are from the Marcellus shale. Figs. 2-6 are enlarged to six diameters.
- Fig. 7. A fragment of the Genesee slate covered with *Styliola fissurella*, enlarged to three diameters.
- All the following figures are enlarged to six diameters unless otherwise indicated.
- Fig. 8. A crushed specimen showing obscure transverse striae; the apex acute.
- Fig. 9. A crushed specimen without visible transverse striae, and with the extremity bulbiform.
- Fig. 10. A specimen in its natural proportions, the margin of the aperture broken away on one side. The surface is obscurely marked by transverse striae, and the extremity slightly bulbiform.
- Fig. 11. An individual which is apparently contracted near the aperture, with the surface faintly striate concentrically, and the apex acute.
- Fig. 12. A smaller form similar to the preceding, without visible transverse striae.
- Fig. 13. A larger compressed specimen with obscure transverse striae.
- Fig. 14. A portion of an individual where the transverse striae are more closely arranged, and more conspicuous.
- Fig. 15. An individual of large size, where the lower part of the tube is essentially smooth, or preserving only obscure concentric striae, while towards the aperture these striae become much stronger, and are cancellated by longitudinal striae; the latter being visible only so far as shown in the figure. All the figures from 11-15 inclusive have no perceptible expansion at the apex.
- Fig. 16, a, b, c. Specimens showing an apparently intermittent mode of growth.
- Fig. 17. A specimen showing the insertion of one individual within another; the outer broken margin being of the shell, and the intermediate portion the filling of mineral matter between the two. It is probable that some of the irregular specimens referred to intermittent growth may be due to conditions similar to fig. 17; but in other examples it is clearly the mode of growth.
- Figs. 18, 19. Two small individuals of regular form and acute apices, with faint, transverse undulations, which are scarcely defined as striae.
- Fig. 20. Three individuals lying in juxtaposition and preserving their natural proportions; two of them show evidence of intermittent growth, and are contracted near the aperture, while the third one is simple. The surfaces are marked by faint undulations or obsolete striae.
- Fig. 21. A short, broad form, the breadth increased by compression.
- Fig. 22. A short, broad specimen with the aperture entire. From the Genesee slate. *Lexington, Indiana.*
- Figs. 23, 24. Two individuals of slightly different shape (fig. 23 being a little more compressed), both of which have the surface distinctly cancellated by fine, longitudinal and transverse striae. Fig. 24 is slightly bulbiform at the extremity, while fig. 23 is acute.
- Fig. 25. A fragment showing the cleavage surface of a calcareous layer in the Genesee slate, which is chiefly composed of *STYLIOLA* with a few *TENTACULITES*. Natural size. *Cayuga creek, Erie county, N. Y.*
- Fig. 25 a. A polished, translucent section from a calcareous layer in the Marcellus shale, showing the transverse and longitudinal sections of *STYLIOLA*; enlarged to three diameters. *Cherry Valley, N. Y.*
- Figs. 26, 27 and 28 are very minute, slender forms of *STYLIOLA* enlarged to six diameters, as in the preceding and following figures of this species. The apices are slightly bulbiform; and on figure 27 there are obsolescent striae, while figures 26 and 28 are smooth. From the compact layer composed of the shells of *Styliola*, in the Genesee slate. *Cayuga creek, Erie county, N. Y.*
- The figures from 7 to 28 inclusive, except 25 a, are from the Genesee slate. The figures 29 and 30, and 33-36, are from the shales in the lower part of the Hamilton group, above the Marcellus shale.

HAMILTON GROUP.

[Marcellus shale & Genesee slate.]

(TENTACULITIDÆ.)

Palæontology of NY Vol V. Pl. II.

Plate XXXIA

PLATE XXXI A—Continued.

STYLIOLA FISSURELLA.

Page 178.

- Figs. 29, 30. Two individuals from the soft calcareous shales of the Hamilton group, presenting the prevailing forms in that horizon, with surfaces entirely smooth. Figure 29 is slightly bulbiform at the apex; figure 30 is acute, presenting a depressed line along the middle of its length, which is due to pressure.
- Figs. 31, 32. Two individuals, enlarged to six diameters, showing strong longitudinal striae, and faint, transverse annulations; the smaller one is slightly expanded at the apex, and the larger one distinctly bulbiform. These specimens are from the calcareous band in the Marcellus shale at Cherry Valley, and are referred to *S. fissurella* var. *strigata*.
- Fig. 33. A more elongate form, where the striae are obsolescent, being barely perceptible under a strong lens, and appearing smooth under ordinary observation. The apex is distinctly bulbiform. This form occurs associated with those of figures 29 and 30, in the calcareous shales of the Hamilton group.

The forms illustrated in figures 29, 30 and 33 are referred to *S. fissurella* var. *obsolescens*. See page 180.

STYLIOLA OBTUSA.

Page 182.

- Fig. 34. A fragment of shale covered with individuals of this form. Natural size.
- Fig. 35. A small specimen with a scarcely perceptible bulbiform apex.
- Fig. 36. A larger individual with the apex bulbiform. The surface is entirely smooth. From the shales of the Hamilton group.

TENTACULITES GRACILISTRIATUS.

Page 173.

- Figs. 37, 38. Specimens of similar character with the apices acute. The specimen, figure 38, is somewhat contracted near the aperture, and free from annulations.
- Figs. 39–42. Specimens of similar character, varying in the proportional number and distance of the annulations, and in the comparative length of the smooth part of the tube towards the apex. The apices are all bulbiform. From the soft shales of the lower part of the Hamilton group.
- Fig. 43. A similar form, where the annulations are more acute, and somewhat unequally distant, with the apical portion marked only by longitudinal striae.
- Fig. 44. A specimen, in the compact limestone of the Marcellus shale, where the annulations are sharply defined and continuing to the extremity, so far as preserved.
- Fig. 45. A small specimen from the Genesee slate, where the annulations are continued nearly to the apex.
- Fig. 46. A fragment of shale, preserving *TENTACULITES* and *STYLIOLA* upon its surface, and presenting the usual conditions, as they occur in the shales of the lower part of the Hamilton group; enlarged to six diameters.
- Fig. 47. A small fragment of shale with the apical portions of *Tentaculites gracilistriatus*, which preserve only slight undulations of the surface, with a single smooth *Styliola*.

TENTACULITES BELLULUS.

Page 169

- Fig. 48. A specimen partially denuded of the shell, the thickness of which is shown on each side of the figure. The annulations are irregular, and the tube contracted towards the aperture; enlarged to two diameters.
- Fig. 49. An individual partially denuded of the shell, and showing distant and irregular annulations. The apex has become solidified from organic deposition, as shown in the lower part of the figure.
- Fig. 50. The apical portion of a specimen, where the annulations are regular and closely arranged throughout. The figure represents the specimen enlarged to two diameters, and the surface is marked by about sixty annulations.
- Fig. 51. A group of individuals of this species, as they occur on the surface of the shale; enlarged to three diameters.

PLATE XXXII.

COLEOLUS ORENATOCINCTUM.

Page 188.

- Fig. 1. A fragment in chert, where the shell is crystallized in silica; natural size. The section below shows the diameter of the tube, and proportional thickness of the shell.
- Fig. 2. An enlargement from a small fragment of another individual in chert, where the surface characters are preserved.
- Fig. 3. An elongate tubular form in limestone, which apparently belongs to this genus and species.
- Fig. 4. A fragment of similar character with the preceding, but more curved and irregular.

COLEOLUS TENUICINCTUM.

Page 189.

- Fig. 5. A small individual which is crushed at the larger end. Owing to the position of the individual, the striæ appear to be directly transverse.
- Fig. 6. A larger flattened specimen, which is fractured longitudinally along the centre of the exposed surface. The striæ are oblique. Figure enlarged.
- Fig. 7. An individual with finely striated surface, the upper end of which is partially inclosed in a striated fold of shale. The striæ on the shale are due to slipping or concretionary action. Enlarged.
- Fig. 8. A small specimen in its natural proportions, enlarged two diameters, showing the slightly expanding cylindrical tube, with its characteristic annulations.
- Fig. 9. A further enlargement of a portion of the specimen figure 8, showing the oblique annulations and fine longitudinal striæ.

CLATHROCÆLIA EBORICA.

Page 204.

- Fig. 10. The exposed face of the specimen in shale, showing the arching septa (or laminæ), with the longitudinal lines obscurely indicated.

HYOLITHES LIGEA.

Page 195.

- Fig. 11. The ventral surface of a specimen, showing the faintly impressed sides with a more strongly convex centre.
- Fig. 12. View of the dorsal side, showing the deeply concave margin of the aperture.
- Fig. 13. Profile view of the same, showing the relative convexity of the two sides of the specimen.
- Fig. 14. The dorsal surface of a specimen. From the Schoharie grit.
- Fig. 15. A transverse section of the specimen, figure 12.
- Fig. 16. A smaller individual of the same species (?) which has been somewhat irregular in its mode of growth.

HYOLITHES PRINCIPALIS.

Page 196.

- Figs. 17-19. Three views of an imperfect specimen, showing the rapid increase in diameter, the relative convexity of the opposite sides, and the arching of the lip of the aperture on the convex side of the shell.
- Fig. 20. The dorsal surface of a large specimen supposed to belong to this species, but showing more angularity along the middle, and a different ratio of increase in width.
- Fig. 21. A transverse section of the specimen, figure 17.

UPPER HOLLERSBERG & MALMSTON GROUPS.

Paleontology of N.Y. Vol. IV. Pl. II

Plate XXII.

PLATE XXXII.—*Continued.*

HYOLITHES ACLIS.

Page 197.

- Fig. 22. The ventral side of a large specimen fractured by compression.
Fig. 23. The opposite side of the same.
Fig. 24. Profile outline of the same, showing the convexity.
Fig. 25. A more expanded and comparatively shorter form. The cavity contains the head of a small DALMANITES.
Fig. 26. A transverse section of a specimen of this species.
Figs. 27, 28. Two different forms of operculum associated with the above, and supposed to belong to the same species.
Fig. 29. An enlarged figure from a specimen of angular form, showing obscure longitudinal striæ, and distinct suture-like lines. In the *Illustrations of Devonian Fossils* this figure (as fig. 9 of Plate XXVII) is erroneously referred to *H. striatus*.

HYOLITHES ACLIS, var. PETALOIDEA.

Page 197.

- Fig. 30. The ventral side, with the central portion depressed, and limited by a distinct angularity on each side.

HYOLITHES STRIATUS.

Page 199.

- Fig. 31. An enlargement of a specimen to three diameters, showing the ventral surface with longitudinal striæ, and the impression of the angular side with characteristic impressed lines.
Fig. 32. An enlargement of the dorsal surface to six diameters, showing the longitudinal striæ.
Fig. 33. A transverse section of a specimen of this species.
Fig. 34. An operculum found associated with the specimens, and supposed, from its form and radiating striæ, to belong to the species.

PLATE XXXII A.

COLEOPRION? TENUIS.

Page 184.

Fig. 1. A specimen in shale, natural size.

Fig. 2. A portion of the same enlarged, showing the longitudinal groove and oblique striae.

COLEOLUS CRENATOCINCTUM.

Page 188.

Fig. 3. A specimen in which the transverse striae or annulations are barely perceptible.

Fig. 4. A piece of limestone preserving portions of several individuals of this species, which are broken longitudinally, showing the interior filling and the thickness of the shell.

COLEOLUS? MOHRI.

Page 189.

Fig. 5. A fragment of an individual imbedded in limestone, showing, in part, the interior cast with the crystalline shell, and the faintly striated impression of the exterior in the lower part of the specimen.

COLEOLUS TENUICINCTUM.

Page 185.

Fig. 6. A specimen, natural size, which is compressed and longitudinally grooved from fracture, at both extremities, while the central portion is more faintly striated, and shows no longitudinal groove.

Fig. 7. An enlargement of a fragment which is strongly striated at one end with a longitudinal depression; the remaining portion being faintly striated, and preserving its natural proportions.

Fig. 8. Another individual, enlarged, showing the smaller extremity much flattened, strongly striated and longitudinally grooved. The central portion is more distinctly striated, without longitudinal groove, while the larger extremity has a slight longitudinal groove and stronger annulations.

Fig. 9. A fragment enlarged. The annulating striae are regular and sharply defined, and the longitudinal groove is evidently due to fracture. The longitudinal striae are likewise shown in the specimen.

Fig. 10. An imperfect specimen, natural size, showing fine, equal and obliquely-annulating striae.

COLEOLUS ACICULUM.

Page 187.

Fig. 11. An individual, natural size, which is flattened upon the surface of a slaty lamina; the lower portion showing a longitudinal line of fracture, with obscure indications of transverse striae near the aperture.

Fig. 12. A similar specimen to the preceding, but less distinctly preserved.

Fig. 13. A fragment of slate, preserving a crushed specimen of this species, and a young, or the smaller extremity of another individual.

Fig. 14. A small or imperfect individual of this species from the green shale of the Portage group, in which occurred the original of *Orthoceras aciculum*.

Fig. 15. A fragment of what appears to be the same species, preserving obscure transverse striae. The specimen is preserved in a soft olive shale. The transverse striae in this figure and in figure 11 are much too strongly represented.

Fig. 16. A crushed and imperfect individual, apparently of this species. The lower part of the imprint shows obscure, cancellating striae.

COLEOLUS (DENTALIUM?) ACICULATUM.

Page 190.

Fig. 17. A fragment of limestone, preserving portions of two individuals. Natural size.

Fig. 18. A part of an individual enlarged, showing the cast of the interior and the thickness of the shell.

HYOLITHES TRILIRATUS.

Page 201.

Fig. 20. The dorsal side of an imperfect individual, imbedded in the rock, showing a double groove along the dorsal angle.

Fig. 22. A large individual, showing a distinct groove along the dorsal angle, with the lateral angles crushed, and the shell partially separated.

HYOLITHES ACLIS.

Page 197.

Fig. 21. The ventral side of a small individual, which is compressed near the margins, and the sides partially separated at what appear to be the suture lines (= var. *petaloidea*).

Fig. 23. The ventral side of a specimen preserved in the coarser shale, and showing longitudinal striæ very distinctly near the lower margin.

Fig. 24. The inner surface of the shell on the ventral side, showing the longitudinal and transverse striæ, and also the longitudinal lines of apparent fracture from compression (= var. *petaloidea*).

Fig. 25. An enlargement of an operculum, supposed to belong to this species, showing the surface characters more in detail than figure 27 of plate 32.

HYOLITHES STRIATUS.

Page 199.

Fig. 26. An enlargement of an operculum, supposed to belong to this species.

HYOLITHES SINGULUS.

Page 202.

Fig. 27. The lower part of an individual of this species, showing the character of the surface-markings, and obtusely triangular form of the shell.

CLATHROCÆLIA EBORICA.

Page 204.

Fig. 28. The exposed flat side of a specimen, showing the arching and recurved septal markings, with some of the longitudinal striæ.

Fig. 29. A larger individual than the preceding, showing the arching, septal markings and the longitudinal striæ. The shell, in the lower part, is crushed, and appears to be separated in distinct arching laminar rings.

PLATE XXXIII.

CONULARIA UNDULATA.

Page 208.

- Figs. 1, 2. Two views of a slightly compressed cast of an imperfect specimen, showing the expansion, and the general characters of the species.
- Figs. 3, 4. The opposite sides of a larger cast, somewhat compressed, showing a more gradual tapering form, with the deeply concave septum truncating the apex.
- Fig. 5. From a gutta-percha impression in the natural mold, the specimen showing a rapidly tapering shell, as in figures 1 and 2, with crowded striae at the lower extremity. The surface is marked by the imprints of several *Discina* which have been attached to the surface. It is possible that further examination, with a larger number of specimens, may prove the form shown in figures 1, 2 and 5 distinct from that of figures 3 and 4.
- Fig. 7. A diagram giving the form of a transverse section of the specimen figures 1 and 2.

CONULARIA CONTINENS.

Page 212.

- Fig. 6. An enlargement of the surface from a well-preserved specimen.

CONULARIA CREBRISTRIATA.

Page 210.

- Fig. 8. A fragment in shale, showing a very gradual expansion of the cone, and very fine crowded transverse striae.
- Fig. 9. Enlargement of the surface, showing the transverse striae apparently destitute of nodes. This appearance may be due to partial exfoliation of the shell.

Page 208.

See Plate 33.

- Fig. 1. An enlargement to six diameters from a gutta-percha impression of a mould of the specimen represented in fig. 5, plate 33.
- Fig. 2. A small specimen with extremely fine transverse striæ, and resembling very closely *Conularia crebristriata*.
- Fig. 3. A transverse section of fig. 2, showing the quadrangular form, with concave sides and indented angles. The specimen is slightly distorted by pressure.
- Fig. 4. An enlargement to six diameters of the surface of the specimen fig. 2, showing the character of the shell surface on the right hand of the figure, and of the cast of the interior on the left, with the somewhat oblique longitudinal striæ.

CONULARIA CREBRISTRIATA.

Page 210.

See Plate 33.

- Fig. 5. An enlargement of the surface of this species to six diameters from the specimen fig. 8, pl. 33, showing the nodes upon the transverse ridges, and the longitudinal striæ. A comparison with the other figures, having the same degree of enlargement, will show the distinctive features of the species.

CONULARIA CONTINENS.

Page 212.

See Plates 33, 34.

- Fig. 6. An enlargement to six diameters, showing the interlocking of the transverse ridges. The nodes are preserved in some parts, and the longitudinal striæ are shown over the entire surface, as they usually appear.

CONULARIA CONTINENS, var. RUDIS.

Page 215.

- Fig. 7. A specimen, natural size, showing the short, abrupt cone, and the strong surface-markings.
- Fig. 8. An enlargement of a portion of the surface of fig. 7, showing the transverse ridges, with the nodes preserved on some parts; while the intermediate, longitudinal striæ are strongly marked.

CONULARIA CONGREGATA.

Page 214.

See Plate 34.

- Fig. 9. An enlargement from the specimen illustrated in fig. 1, pl. 34, showing the strong and somewhat irregular, nodose, transverse ridges, and the intermediate, longitudinal striæ, which are usually obscure or obsolete.
- Fig. 10. An enlargement from another portion of the surface of the same specimen, on which the transverse ridges are almost free from nodes, and the longitudinal striæ are obscurely visible; probably due to maceration or exfoliation.
- Fig. 11. An enlargement from another specimen of the same species, showing the transverse ridges almost entirely free from, or obscurely marked by, nodes, while the intermediate, longitudinal striæ are continuous and well preserved.

CONULARIA NEWBERRYI.

- Fig. 12. An enlargement to two diameters of the transverse ridges, showing their delicately annular character, and the manner of their junction along the centre of the lateral face. The figure is given for comparison with a similar portion of the surface of *C. continens*, fig. 6.

PLATE XXXVIII.

ORTHOCERAS SICINUS.

Page 301.

- Fig. 1. A fragment showing the form and proportions of the shell, with the obscure annulations and surface-markings. The annulations are not represented sufficiently distinct. Marcellus shale. *Aron, N. Y.*
- Fig. 2. An enlargement of the surface of the preceding specimen, showing the rounded annulations and reticulate surface.

ORTHOCERAS SUBULATUM.

Page 283.

See Plates 84, 86.

- Fig. 3. The original of the species, which is nearly entire, preserving the chamber of habitation. The specimen is flattened from pressure in the shale. Marcellus shale. *Bloomfield, N. Y.*

ORTHOCERAS MARCELLENSE.

Page 278.

See Plate 83, 113.

- Fig. 4. A fragment preserving several of the air-chambers, and a portion of the test with the external markings.
- Fig. 5. The ventral side of a larger fragment retaining portions of the test over the surface, and the carina on the internal mould, which is too prominently represented along the chamber of habitation towards the aperture.
- Fig. 6. A nearly entire individual showing the length of the outer chamber and the increase in the frequency of the septa toward the apex. The peculiar organic deposit and ornamentation of the internal cast, shown in the specimen, are not represented in the figure. The apex is represented as entire, but several air-chambers are wanting in the specimen.
- Fig. 7. A larger example, imperfect at both extremities, retaining fragments of the test on different parts of the surface.
- Fig. 9. An enlargement of the surface, showing the transverse striæ interrupted by longitudinal lines.

The above specimens are all from the Goniatite limestone of the Marcellus shale. *Manlius, Marcellus*, and other places in New York.

ORTHOCERAS APTUM.

Page 282.

- Fig. 8. An individual preserving the greater portion of the chamber of habitation, and over thirty air-chambers, showing the gradually enlarging tube, and the curved and oblique septal sutures: dorsal view. Goniatite limestone. *Manlius, N. Y.*

ORTHOCERAS BEBRYX.

Page 275.

See Plates 39, 83, 84.

PLATE XLI.

ORTHOCERAS THOAS.

Page 261.

See Plates 78 B, 79, 80, 112.

- Fig. 1. A compressed fragment of the outer chamber, which is more closely annulated than usual, showing longitudinal striae in some parts.
- Fig. 2. A similar specimen, showing striae upon some parts of the surface. This and the preceding are from the limestone of the Upper Helderberg at *Schoharie, N. Y.*
- Figs. 3, 4. Specimens preserving the outer chambers, which are scarcely compressed, with the annulations more distant than in the preceding specimens. The surface preserves the longitudinal striae. These specimens are from the Schoharie grit, and are the originals used in the description of *O. Thoas. Schoharie, N. Y.*
- Fig. 5. The non-septate portion of a small individual, preserving the cylindrical form and the more frequent annulations, except at the upper end. From the Schoharie grit. *Schoharie, N. Y.*
- Fig. 6. A large non-septate portion of a specimen retaining the natural form, and showing closely arranged annulations in the lower part, which gradually increase in distance toward the aperture, where they are much more distant. Schoharie grit. *Schoharie, N. Y.*
- Fig. 7. A septate fragment with the annulations closely arranged, and more angular than usual. This specimen is the original of *O. Hyas. Schoharie grit. Schoharie, N. Y.*
- Fig. 8. A small uncompressed, septate portion of an individual, showing the regularity of the septa and annulations. From the Upper Helderberg limestone at *Clarence Hollow, Erie county, N. Y.*
- Fig. 9. A fragment of a large individual referred with doubt to this species. The specimen is much compressed, and preserves no remains of the surface ornaments. The obliquity of the annulations is apparently due to the flattening of the shell. From the Corniferous limestone of *Ohio.*

PLATE XLII.

ORTHOCERAS CROTALUM.

Page 296.

See Plates 82, 113.

- Fig. 1. A portion of the chamber of habitation, showing the absence of annulations near the aperture, and the strong, lamellose, striate surface of the internal mould. *Schoharie county, N. Y.*
- Fig. 2. A specimen similar to the preceding, with the annulations more prominent, and slightly oblique. *Pratt's Falls, N. Y.*
- Fig. 3. A fragment somewhat compressed, showing the marked annulations, and the depth of the air-chambers. *Cazenovia, N. Y.*
- Fig. 4. A more slender specimen, showing the amount of compression, and the obliquity of the annulations, with the septal sutures intersecting them by planes oblique to the axis of the tube, and to the direction of the annulations. *Cazenovia, N. Y.*
- Fig. 5. A small, septate fragment, preserving the characteristic, fine, longitudinal striæ over the exterior of the tube. *Hamilton, N. Y.*
- Fig. 6. The chamber of habitation nearly entire, showing the absence of annulations near the aperture, and a portion of a broad retral curve in the annulations over one side.
- Fig. 7. A fragment showing the increase in the distance and prominence of the annulations from the apex toward the outer chamber. *Otisco Lake, N. Y.*
- Fig. 8. A compressed fragment, exhibiting the same characteristics as the preceding specimen. *Hamilton, N. Y.*
- Fig. 9. A lateral view of the same, showing the amount of compression.
- Fig. 11. A portion of the surface enlarged from specimen fig. 5, showing the fine, regular, longitudinal striæ. Two of the septal sutures are shown in the upper furrow.
- Fig. 12. A fragment of a large individual with more distant annulations. *Geneseo, Livingston county, N. Y.*

ORTHOCERAS CÆLAMEN.

Page 298.

See Plates 43, 82, 113.

Plate XLII.

PLATE XLIV.

GOMPHOCERAS EXIMIUM.

Page 329.

Fig. 1. An individual slightly compressed, preserving a large portion of the chamber of habitation and thirteen air-chambers; showing the gibbosity of the shell and the slope of the sides toward the aperture. *Columbus, O.*

Fig. 2. A smaller individual, much disturbed by compression, and showing some variation in the depth of the air-chambers, compared with the preceding.

The specimen is from the lower limestone of the Upper Helderberg group, in the vicinity of *Buffalo, N. Y.*

PLATE XLV.

GOMPHOCERAS OVIFORME.

Page 344.

See Plates 46, 94.

- Fig. 1. A view of the aperture of a specimen showing the comparative size and relations of the large and small apertures. Goniatic limestone of the Marcellus shale, near *Manlius*, N. Y.
- Fig. 2. Dorsal view of a specimen, showing the general form of the shell and the truncated apex. The apical portion is not fully represented, the specimen preserving considerable more of the test covering the apex than is represented in the figure. A fragment of the test is preserved on the chamber of habitation, showing the fine, lamellose lines of growth. Goniatic limestone. *Schoharie*, N. Y.
- Fig. 3. The aperture of the preceding specimen, which is somewhat larger in proportion to the diameter of the tube than in the specimen shown in fig. 1.
- Fig. 4. A view of the aperture of another individual, which exhibits a considerable variation from the preceding specimens in the position of the aperture and the non-symmetrical arrangement of the large and small apertures. Goniatic limestone. *Schoharie*, N. Y.

GOMPHOCERAS FISCHERI.

Page 336.

- Fig. 5. Lateral view of an individual, showing its fusiform shape and the crenulated zone at the base of the chamber of habitation, with the furrows continued over the walls of the air-chambers. A fragment of the test, showing the surface-markings, is preserved over a small portion of the air-chambers. The apical portion is partially restored, and represents a much smaller apical angle than is indicated in the other specimens of the species. Goniatic limestone, near *Manlius*, N. Y.
- Fig. 6. Represents a fragment of another specimen from the same locality, preserving the shell over the entire surface of the tube, and showing the broad sinus of the striae over the ventral side.

Plate XLV.

PLATE XLVI.

GOMPHOCERAS CONRADI.

Page 348.

- Fig. 1. Lateral view of a small individual, showing the endogastric curvature of the tube, the furrows of the crenulations at the base of the chamber of habitation, and the concentric striae of the test over the septate portion. Goniatile limestone. *Manlius, N. Y.*
- Fig. 2. Ventral view of the preceding, showing the small aperture and the form of the shell.
- Fig. 3. Ventral view of the chamber of habitation of a larger individual, showing the constriction of the tube near the aperture, and the narrow, crenulated zone at the base. Goniatile limestone. *Manlius, N. Y.*

GOMPHOCERAS BETA.

Page 326.

- Fig. 4. An individual considerably compressed, preserving the greater portion of the chamber of habitation and air-chambers. The curvature of the sutures is due to compression. Schoharie grit. *Schoharie, N. Y.*
- Fig. 5. Ventral view of the chambered portion of another individual, showing the impression left by the removal of the siphuncle in the process of weathering. Schoharie grit. *Schoharie, N. Y.*

GOMPHOCERAS OVIFORME.

Page 314.

See Plates 45, 94.

- Fig. 6. A small, globose individual, showing the general form of specimens of this size. The epidermal layer of the test has been exfoliated at the apical portion of the tube, showing the markings and structure of the nacreous layer. Goniatile limestone. *Schoharie, N. Y.*
- Fig. 7. An enlargement of the surface of the apical portion of the preceding, showing the characters of the nacreous layer of the test.

GOMPHOCERAS ABSENS.

Page 324.

- Fig. 8. Lateral view of a fragment showing the curvature of the tube. Schoharie grit. *Schoharie, N. Y.*
- Fig. 9. Ventral view of the preceding, showing the enlargement of the tube, the regularity of the air-chambers, and the impression of the siphuncle, which has been removed in the process of weathering.

PHRAOMOCERAS? EXPANSUM.

- Figs. 10, 10. This specimen is erroneously figured on this plate as from the Hamilton, but belonging to the Coralline limestone of the Niagara group. *See Addenda for explanation.*
- The representation of the siphuncle is incorrect; the specimen shows it to be on the concave side of the tube.

CYRTOCERAS ALTERNATUM.

Page 365.

- Fig. 12. Ventral view, showing the undulations of the tube and the siphuncle, as exposed in the process of weathering. The undulations and rounded nodes on the tube are not fully represented in the figure. Goniatile limestone. *Schoharie, N. Y.*
- Fig. 13. Lateral view of the preceding, showing the curvature of the tube.

GOMPHOCERAS CLAVATUM.

Page 323.

See Plate 93.

- Fig. 14. Lateral view, showing the endogastric curvature of the tube and the comparative convexity of the dorsal and ventral sides. Schoharie grit. *Albany county, N. Y.*
- Fig. 15. A view of the convex-dorsal side of the preceding, showing the form of the tube and the depth of the air-chambers.

CYRTOCERAS MORSUM.

Page 367.

Fig. 3. Ventral view of a fragment which is imperfect at the apex, showing traces of the transverse costæ of the test and the slight sinus along the ventrum.

Fig. 4. Lateral view of the preceding, showing the curvature of the tube. This specimen is the type of the species, and is from the Upper Helderberg limestone. *Clarence Hollow, N. Y.*

CYRTOCERAS EUGENIUM.

Page 369.

See Plates 36, 96, 97.

Fig. 5. Lateral view of an individual nearly entire, showing the straight outer portion and curved apex. Several fragments of the test, preserving the surface-markings and ornaments, are adhering to parts of the tube. The internal mould preserves the furrows of the crenulations and the annulations marking the exterior ridges of the test.

Fig. 6. Ventral view showing the sinus of the ornaments and aperture, with the variation in the prominence and frequency of the annulations and transverse ridges toward the apex and near the aperture.

Fig. 7. Dorsal view of the straight portion of a large individual showing a slight gibbosity, due to the gradual contraction of the tube toward the aperture. The dorsal margin of the aperture is shown to be continuous and entire. In this example the prominent expansions of the test become obsolescent toward the aperture, where the shell is marked by lamellose lines of growth. These specimens are from the Upper Helderberg limestone, at *Schoharie, N. Y.*

Plate LIV.

PLATE LV.

GYROCERAS MATHERI.

Page 377.

- Fig. 1. Front view of the internal mould of an individual, showing the character of the annulations on the dorsal side of the outer volution, and the sinus of the ornaments on the ventral side of the apical portion.
- Fig. 2. Lateral view of the preceding, showing the volutions and the enlargement of the tube. The annulations and furrows of the crenulations are also shown. Upper Helderberg limestone, near *Catskill*, N. Y.
- Fig. 3. Ventral view of a larger individual, showing the sinus of the annulations on the internal mould, and the extension of the transverse lamellæ into the surrounding matrix. Small fragments of the test are preserved on a portion of the tube, showing the surface-markings. *Schoharie*, N. Y.
- Fig. 4. Lateral view of the preceding, showing the curvature of the tube and the frequency of the annulations. This specimen exhibits a common tendency of the last half of the outer volution to become straight, and directed outward from the general curve of the spire.
- Fig. 5. A fragment showing more closely coiled volutions. The larger extremity shows the concave surface of a septum; but the longitudinal section, as represented, preserves no evidences of the air-chambers or siphuncle. *Schoharie*, N. Y.
- Fig. 6. A septum showing the transverse section of the tube.

UPPER HELDERBERG GROUP.

Palæontology of N.Y. Vol. IV. Pt. II.

Plate LV

PLATE I

PLATE I. (continued)

1. A large, elongated, somewhat flattened, and slightly curved object, possibly a fossilized bone or a piece of wood, showing a series of parallel lines or ridges along its length. It is approximately 10 cm long and 2 cm wide.

2. A smaller, more rounded object, possibly a fossilized bone or a piece of wood, showing a series of parallel lines or ridges along its length. It is approximately 5 cm long and 1 cm wide.

3. A small, rounded object, possibly a fossilized bone or a piece of wood, showing a series of parallel lines or ridges along its length. It is approximately 2 cm long and 1 cm wide.

PLATE I. (continued)

4. A small, rounded object, possibly a fossilized bone or a piece of wood, showing a series of parallel lines or ridges along its length. It is approximately 2 cm long and 1 cm wide.

5. A small, rounded object, possibly a fossilized bone or a piece of wood, showing a series of parallel lines or ridges along its length. It is approximately 2 cm long and 1 cm wide.

6. A small, rounded object, possibly a fossilized bone or a piece of wood, showing a series of parallel lines or ridges along its length. It is approximately 2 cm long and 1 cm wide.

PLATE LVI.

GYROCERAS TRANSVERSUM.

Page 384.

- Fig. 1. Lateral view of a large fragment, showing the curvature and enlargement of the tube, and the rows of rounded nodes over the chambered portion. The strong test is shown covering the dorsal side of the tube. The arching, transverse striæ, represented on the chamber of habitation, do not exist on the specimen. Goniatile limestone of the Marcellus shale. Near *Manlius*, N. Y.
- Fig. 2. Ventral view of the preceding, showing the sinus in the margin of the aperture, the crenulated zone at the base of the grand chamber, and the profile of the nodes on the sides of the tube.
- Fig. 3. Ventral view of a smaller septate fragment, showing the variation in the depth of the air-chambers toward the apex, and a longitudinal, flattened band along the ventrum. Goniatile limestone. Near *Manlius*, N. Y.
- Fig. 4. A septum of the preceding, showing the size and position of the siphuncle on the convex ventral side of the tube.

NAUTILUS LIRATUS, var. JUVENIS.

Page 411.

- Fig. 5. The dorsal side of the specimen, preserving the grand chamber and several imperfect air-chambers, showing the broad elliptical aperture, and the slender, carinate revolving striæ, with fine transverse striæ. The position of the siphuncle cannot be satisfactorily determined, and is not represented. Hamilton shales. *Cazenovia*, N. Y.
- Fig. 6. The ventral side of the same specimen, showing the revolving striæ much subdnded, while the transverse striæ are essentially the same as on the opposite side. The specimen is free from weathering or wearing, and the surface-markings are in their natural condition.

PLATE LVII.

GOMPHOCERAS? PLANUM.

Page 352.

- Fig. 1. The ventral side of a fragment of the species, carrying seven air-chambers and the base of the chamber of habitation.
- Fig. 2. The convex side of a septum, showing the size and position of the siphuncle. *Borodino, Skaneateles lake, N. Y.*

NAUTILUS LIRATUS.

Page 407.

See Plate 60.

- Fig. 3. A lateral view of a partially compressed specimen, which is a cast of the interior, preserving only strong, revolving plications, of which there are nine on the lateral face of the chamber of habitation. *Hamilton group. Quarries north of Sherburne, Chenango county, N. Y.*

NAUTILUS SUBLIRATUS.

Page 409.

- Fig. 4. A dorso-lateral view of a fragment, which preserves the greater part of the chamber of habitation and four of the attached air-chambers. The specimen is a cast of the interior, obliquely compressed, showing one-half of the dorsal side and a portion of the lateral face, and preserving five revolving plications.
- Fig. 6. The ventral side of the grand chamber, with a few attached air-chambers. The central space is concave and essentially smooth, while on each side there are six revolving, angular plications. The transverse striæ are partially preserved.
- Fig. 7. The ventral side of the preceding specimen, which preserves the evidence of several air-chambers at the base, the surface being marked by fine, sharply impressed, longitudinal striæ, which are cancellated by finer transverse striæ; but without any indication of the revolving ridges or plications. *Earlville, Madison county, N. Y.*
- Fig. 5. A fragment of the chambered portion of a *Nautilus*, which is referred with doubt to this species. It is much larger than the chambered portion of any other individual which has been observed. The radiating plications which are so well defined in this specimen are barely perceptible, or obsolescent on the smaller individuals referred to this species. *Hamilton group. Basin Gulf, Skaneateles lake, N. Y.*

PLATE LVIII.

GYROCERAS ERYX.

Page 386.

See Plate 103.

Fig. 1. A septate fragment of this species, showing the curvature of the tube and the depth of the air-chambers. From Dolomitic limestone, referred to the Hamilton group, near *Milwaukee, Wis.*

TROCHOCERAS ORION.

Page 397.

Fig. 2. Lateral view of a fragment, showing the curvature of the tube, the gibbous chamber of habitation becoming straight, and contracting near the aperture. The sinus represented on the dorsal side of the aperture is incorrect, and is not shown on the specimen. A broad sinus in the ventral margin corresponds to the sinus of the surface-markings on the convex side of the tube. Schoharie grit. *Helderberg mountains, N. Y.*

TROCHOCERAS EUGENIUM.

Page 396.

See Plate 59.

Fig. 3. Lateral view of a small, compressed specimen, showing the curvature of the tube and the depth of the air-chambers. Schoharie grit. *Schoharie, N. Y.*

Fig. 4. A small, compressed, septate fragment, referred to this species with doubt. The air-chambers are shallower than is usual in the species, and it may belong to the apical portion of *Gyroceras spinosum*, but does not preserve any remains of the revolving rows of spines. The obliquity of the septa and the slight deflection of the tube may be due to compression.

TROCHOCERAS OBLIQUATUM.

Page 401.

See Plate 111.

Fig. 5. The concave dorsal side of a specimen, showing the transverse section of the tube and the want of symmetry in the curvature. The view is looking upon the specimen obliquely, which somewhat exaggerates the departure of the curvature from one plane. Schoharie grit. *Schoharie, N. Y.*

TROCHOCERAS EXPANSUM.

Page 402.

See Plate 111.

Fig. 6. The concave dorsal side of a compressed septate fragment, showing the depth of the air-chambers, the curvature of the sutures, and the slight departure of the volution from one plane. Schoharie grit. *Schoharie, N. Y.*

TROCHOCERAS PANDION.

Page 400.

See Plate 111.

Fig. 7. Lateral view of a fragment, showing the angular form of the tube, the depth of the air-chambers, and the obliquity of the septa. Traces of the siphuncle are seen on the convex ventral side as exposed in the process of weathering. Schoharie grit. *Schoharie, N. Y.*

Fig. 8. Lateral view of a specimen preserving about one volution, showing the curvature and form of the shell. The apical portion is much compressed, and the evidences of the air-chambers obliterated. Schoharie grit. *Schoharie, N. Y.*

Fig. 9. A septum of a fragment, showing the transverse section of the tube and the position of the siphuncle. Schoharie grit. *Schoharie, N. Y.*

PLATE LIX.

TROCHOCERAS CLIO.

Page 392.

See Plate 111.

- Fig. 1. The upper side of the internal mould of an individual, showing the depth of the air-chambers, and the extent of the grand chamber. The impression of one of the inner volutions is retained, showing the surface ornaments.
- Fig. 2. The umbilical side of an individual, showing the diameter of the umbilicus, and the annulations and revolving striæ of the test. The septal sutures are less frequent, and oblique to the annulations.
- Fig. 3. Profile view of the preceding, showing the deflection of the volutions.
- Fig. 4. The concave dorsal side of the chamber of habitation, showing the transverse section of the tube; the position of the small siphuncle which is surrounded by an obscure areola, and the surface-characters on the inner side of the volution.
- Fig. 5. A small individual nearly entire, showing the form of the shell, the number of volutions, and the height of the spire.
- Fig. 9. A large individual, showing the numerous continuous annulations, and the gradually enlarging tube. The annulations are rounded on the outer volution, and are wanting on the chamber of habitation. The specimens of this species are from the Schoharie grit, at *Schoharie, N. Y.*

TROCHOCERAS DISCOIDEUM.

Page 394.

- Fig. 6. Upper lateral view of a small individual, showing the depressed spire, the enlargement of the tube, the linear, transverse, annular nodes, and the revolving striæ of the test.
- Fig. 7. The same view of a larger specimen, showing stronger undulations of the tube, with several septa near the apex.
- Fig. 8. The umbilical side of an example, showing the rapidly enlarging tube and the broad, shallow umbilicus. Schoharie grit. *Schoharie, N. Y.*

TROCHOCERAS EUGENIUM.

Page 396.

See Plate 58.

- Fig. 10. A view of the upper lateral side of an individual, preserving the grand chamber and a part of the septate portion, the whole forming a little more than an entire volution, and showing the outer half of the grand chamber produced beyond the inner volution, in a straight line, and not following the curvature of the spiral axis.
- Fig. 11. A similar view of a larger individual, showing the gibbous form of the shell and the contraction of the tube toward the aperture. Schoharie grit. *Schoharie, N. Y.*

Palæontology of N.Y. Vol. V. Pl. II.

Plate LIX.

PLATE LX.

NAUTILUS BUCINUM.

Page 412.

See Plates 106, 107, 109.

- Fig. 1. The dorsal side of a specimen which preserves the inner volutions, and shows the wide aperture.
Fig. 2. The same specimen, with the inner volution removed, showing the form of transverse section, position of siphuncle, and surface-markings.
Fig. 3. A lateral view of the preceding specimen. From the Goniatile limestone, near *Manlius*, N. Y.
Fig. 4. A dorsal view of a larger individual, showing the form of aperture and section of the inner volutions. Several of the air-chambers are broken away, and the position of the siphuncle is shown on the convex and concave surfaces of the septa. Near *Solsville*, *Madison county*, N. Y.

NAUTILUS CORNULUM.

Page 414.

- Fig. 5. A ventral view of the specimen, showing the more circular form of section and of the aperture.
Fig. 6. A lateral view of the preceding specimen, showing the suture lines of the chambered portion of the shell, and the undulating striæ of growth over the surface of the grand chamber. Near *Cazenovia*, N. Y.

GOMPHOCERAS ——— sp.

- Fig. 7. A lateral view of a fragment, showing a moderate degree of curvature and preserving eight air-chambers, with the base of the chamber of habitation. *Shore of Skaneateles lake*, N. Y.

NAUTILUS LIRATUS.

Page 407.

See Plate 57.

- Fig. 8. A figure of a gutta-percha impression, from the mould left in the matrix by the specimen fig. 9, showing the strong revolving plications and the obscure annulations near the apex.
Fig. 9. A specimen preserving the greater part of the chambered portion of the shell in its natural proportions. Several low, transverse undulations are shown toward the apex, and the septal lines are visible beneath the partially exfoliated shell. The revolving plications, which are very prominent near the apex, and are continuous on the concave dorsal side, become obsolete on the ventral side as they approach the chamber of habitation. From the Goniatile limestone. *Schoharie*, N. Y.

PLATE I

1. The first of the series of teeth shown in this plate is a specimen of a tooth from the lower jaw of a human being. It is a central incisor, and is shown in its natural position, with the root and crown clearly visible. The root is straight and tapers slightly towards the apex. The crown is broad and slightly notched at the incisal edge. The enamel is a pearly white color, and the dentin is a light yellowish-brown color. The pulp chamber is located in the center of the crown, and the pulp root extends down the length of the root. The root is surrounded by a layer of alveolar bone, and the crown is surrounded by a layer of gingiva. The tooth is shown in its natural position, with the root and crown clearly visible. The root is straight and tapers slightly towards the apex. The crown is broad and slightly notched at the incisal edge. The enamel is a pearly white color, and the dentin is a light yellowish-brown color. The pulp chamber is located in the center of the crown, and the pulp root extends down the length of the root. The root is surrounded by a layer of alveolar bone, and the crown is surrounded by a layer of gingiva.

2. The second of the series of teeth shown in this plate is a specimen of a tooth from the lower jaw of a human being. It is a central incisor, and is shown in its natural position, with the root and crown clearly visible. The root is straight and tapers slightly towards the apex. The crown is broad and slightly notched at the incisal edge. The enamel is a pearly white color, and the dentin is a light yellowish-brown color. The pulp chamber is located in the center of the crown, and the pulp root extends down the length of the root. The root is surrounded by a layer of alveolar bone, and the crown is surrounded by a layer of gingiva. The tooth is shown in its natural position, with the root and crown clearly visible. The root is straight and tapers slightly towards the apex. The crown is broad and slightly notched at the incisal edge. The enamel is a pearly white color, and the dentin is a light yellowish-brown color. The pulp chamber is located in the center of the crown, and the pulp root extends down the length of the root. The root is surrounded by a layer of alveolar bone, and the crown is surrounded by a layer of gingiva.

Plate LXXX.

PLATE LXXXI.

ORTHOCERAS PRAVUM.

Page 255.

See Plates 35, 36, 112.

- Fig. 1. An individual, preserving the base of the chamber of habitation and eight adjacent chambers. The specimen is much flattened and distorted from compression; the chambers have become partially separated along one side, and their normal form much modified. *Clarksville, N. Y.*
- Fig. 2. A septate fragment, showing the regularity in the depth of the chambers and the gradual enlargement of the tube. The lower portion has been flattened, producing a longitudinal furrow, as represented in the figure, probably from the infolding and subsequent erosion of the shell. The ornamentation on the margins of the septa and on the chamber walls is not shown in the figure.
- Fig. 3. A small fragment of five chambers, showing the concave and convex chamber walls, as produced by compression. *Schoharie, N. Y.*
- Fig. 4. A longitudinal section of three of the chambers of the preceding specimen, showing the indentations in the septa made by the siphuncle. No traces of the siphuncle, in its passage through the chambers, can be observed. The figure does not quite correctly represent the depth of the chambers, and is not complete above.
- Fig. 5. Ventral view of two chambers from the upper portion of the specimen figure 2, showing the extension of the areola to the margin of the septa, and its surrounding with concentric striæ.
- Fig. 6. The apical portion of an individual, presenting the appearance of a gradual absorption and final truncation of the shell. The siphuncle has become exposed from the process of weathering. Sharp longitudinal striæ, partially represented, but shown over several chambers, are probably the remains of the ornamentation or vascular markings on the septa. *Schoharie, N. Y.*
- Fig. 7. A septum, showing the areola and its striæ surrounding the siphuncle and extending to the ventral margin.
- Fig. 8. Another example, similar to the preceding, somewhat enlarged.

ORTHOCERAS OPPLETUM.

PLATE CV.

NAUTILUS MAGISTER.

Page 422.

See Plates 62, 107, 108.

Fig. 1. A fragment, preserving two of the air-chambers near the base of the grand chamber, with one of the smaller ones at the distance of half a volution; the impressions of the intervening air-chambers and septa being marked upon the adhering matrix, showing the re-entrant character of the volutions and the sinus in the septa on the dorsal side. The comparative diameter of the two volutions, as presented in the fragment, are about as 65-115. The convex surface of the larger air-chamber is flattened and distorted from compression and weathering, which obscures the siphuncle: from the same cause the concavity of the dorsal side of the large chambers has been partially obliterated, as shown in the outline of the figure.

The specimen is referred with some hesitation to *N. magister*; but the proportions of the parts are essentially the same as in typical specimens of that species, and it is quite distinct from any other form. Lower part of the Hamilton group. Near *Leonardsville*, *Madison county*, *N. Y.*

NAUTILUS ORIENS.

Page 420.

See Plate 61, 106.

The ventral side of a compressed and imperfect chamber of habitation, with several air-chambers at the base. The shell is partially preserved on one side, showing the transverse lamellose striæ, and the impression of the same on the other side, which is exfoliated, showing numerous plumose, branching Bryozoans which have adhered to the inner surface of the shell. From the *Marcellus shale*. Near *Richmondville*, *Schoharie county*, *N. Y.*

- Fig. 2. A posterior view of the same specimen looking upon the ventral side of the air-chambers, and showing the great width of the chamber of habitation. *Hamburgh, Erie county, N. Y.*

GROUP.

E.)

Plate CVIII.

PLATE CIX.

NAUTILUS BUCINUM.

Page 412.

See Plates 60, 106, 107.

Fig. 1. A ventral view of the grand chamber of a young shell, preserving the surface ornamentation in a remarkable degree of perfection. The sharp, elevated, revolving striae, with finer intermediate transverse striae, are precisely of the character of those on the surface of the specimen of this species from the Goniatite limestone, plate 60, figs. 1-3.

This surface-marking resembles that of the specimen referred to *N. liratus*, var. *juvenis*, figs. 5 and 6, pl. 56, but the revolving striae are more closely arranged and less conspicuous on the concave side, while the tube is free from any transverse undulations which mark that variety. *West shore of Canandaigua lake, N. Y.*

Fig. 2. A fragment preserving the chamber of habitation nearly entire and two attached air-chambers. The surface is marked by the undulating striae of growth and very fine revolving striae. On the concave side of the specimen the revolving striae are about one mm. distant from each other; and on the convex side there are stronger striae of about the same or a greater distance apart, between which are finer striae. From the arenaceous shales of the Hamilton group. Near *Cazenovia, N. Y.*

Fig. 3. An enlargement from the dorso-lateral surface of a specimen of this species, showing the distant revolving striae and the finer concentric striae. From the dark colored shales. *Shore of Cayuga Lake, N. Y.*

NAUTILUS ACRÆUS.

Page 417.

Fig. 4. The ventral side of the chamber of habitation, showing the form (which is slightly compressed), and the fine equal striae of the surface.

Fig. 5. The concave dorsal side, showing the form of the transverse section, the position of the siphuncle, and the fine surface-markings. There is a slight indentation near the upper fractured edge of the shell, which has apparently been produced by the contact of the inner volution.

Fig. 6. An enlargement of the surface, showing the fine, nearly equal striae, of which there are from twelve to fifteen in the space of five mm. In the arenaceous shales of the Hamilton group. *Plainfield, Otsego county, N. Y.*

GONIATITES VANUXEMI.

Page 434.

See Plates 66, 67, 68, 69, 74, 109.

Fig. 7. A transverse section of the disc, showing the form of the inner volutions, their gradually increasing dorso-ventral diameter, and final form in the grand chamber near the aperture.

Fig. 8. A portion of the periphery of a large individual of the species, showing the deep sinuosity in the striae, and their great thickness and imbricating character upon the angles of the periphery. From the Goniatite limestone. *Manlius, N. Y.*

NAUTILUS (DISCITES) MARCELLENSIS.

Page 423.

See Plate 65.

Fig. 9. A small individual of this species, which is principally a cast of the interior, preserving the shell upon a part of the grand chamber, which should have been represented as broken along the peripheral angle. *Manlius, N. Y.*

HAMILTON GROUP.

(NAUTILIDÆ
&
GONIATITIDÆ.)

Palæontology of NY Vol. IV. Pl. II.

Plate CIX.

PLATE CIX.—*Continued.*

- Fig. 10. A lateral view of the cast of a specimen. The adhering shell preserves only the transverse striæ of growth in a nearly obsolete condition. This is the typical specimen of the species described by Mr. VANUXEM. It was originally nearly covered and inclosed in the grand chamber of a large individual of *Goniatites Vanuxemi*. This condition of the specimen was doubtless the source of the error which led to regarding this one as the larger and "more abundant" form, while it never reaches one-half the size of *G. Vanuxemi*, and is far less numerous in individuals. *Manlius, N. Y.*
- Fig. 11. A transverse section of a volution, showing the position of the siphuncle, form, etc. The sides are more convex than usual, and the carinations at the umbilical angles are a little too attenuate—being stronger in the original.
- Fig. 12. An enlargement of the surface, showing the continuous transverse striæ and the interrupted revolving striæ, as appearing on the surface of the specimen fig. 9.

PLATE CX.

NAUTILUS (DISCITES) INOPINATUS.

Page 426.

- Fig. 1. A lateral view of the specimen, showing the wide umbilicus, the form of the volutions, and the rows of nodes upon the umbilical and peripheral margins. The surface is obscured by adhering STROMATOPORA.
- Fig. 2. The ventral side of the specimen, which preserves a part of the shell, obscurely showing the surface-markings. Near *Sandusky, Ohio*.

GONIATITES PLEBEIFORMIS.

Page 443.

See Plate 16.

- Fig. 3. A young specimen preserving the chamber of habitation only, the inner volutions having been dissolved by iron pyrites.
- Fig. 4. A larger specimen, the form and proportions being given from a gutta-percha cast in a natural mould of the fossil. The impressions of the nodes have been only partially preserved.
- Fig. 5. The outer volution of a large specimen preserving only the grand chamber; the septate portion having been removed by the action of iron pyrites.
- Fig. 6. The ventral side of an interior volution, showing the course of the septa and the angular re-entrant lobe.
- Fig. 7. A section of a specimen of the prevailing size and proportions, showing the depth of the chamber of habitation, terminated with the last septum of the chambered portion of the shell. The inner volutions have all disappeared, and the space is occupied by calcareous matter filled with STYLIOLA and TENTACULITES.
- Fig. 8. A section of a specimen, cut in the direction of the spire, preserving the grand chamber and a small part of one of the chambered volutions. The remaining portion of the cavity is filled with limestone containing STYLIOLA.
- Fig. 9. A section of a specimen cut vertically through the spire and the adhering limestone. The section of the outer volution is preserved, as shown in the figure, while the inner turns have been dismembered and displaced, as shown by the small semi-elliptical sections preserved in the central portion of the figure. The septate portions of the volutions are rarely preserved. *Cherry Valley, N. Y.*

- Fig. 4. A specimen in the same association with the preceding, preserving the test over the entire surface, showing the regular, rounded, transverse striae and the gradually enlarging tube.

ORTHOCERAS VARUM.

Page 259.

See Plate 79.

- Fig. 5. Lateral view of a specimen, showing a common appearance of the aperture, due in part to compression. The shell is naturally fusiform, and the chamber of habitation somewhat gibbous. Schoharie grit. *Schoharie, N. Y.*
- Fig. 6. A septum of the preceding, showing the transverse section of the tube, and the small size and central position of the siphuncle.

ORTHOCERAS THOAS.

Page 261.

See Plates 41, 78 B, 79, 80.

- Fig. 7. A large and very much compressed individual, showing a slight curvature of the tube, with the displaced siphuncle, indicated by the raised and curved longitudinal ridge. The maceration of the shell and the destruction of the septa has probably allowed the siphuncle to fall against the interior walls of the tube, and the extreme compression has shown it in relief on the exterior. Upper Helderberg limestone. *Caledonia, N. Y.*
- Fig. 8. An enlargement of the surface to three diameters, showing the sharp, continuous, longitudinal ridges, and the finer transverse striae crenulating their summits. Upper Helderberg limestone. *Dublin, O.*

ORTHOCERAS INOPTATUM.

Page 267.

See Plate 37.

- Fig. 9. A fragment preserving its normal form and retaining portions of the test over the surface of the tube. Upper Helderberg limestone. *Clarence Hollow, N. Y.*
- Fig. 10. The surface of the test enlarged to three diameters, showing the regular longitudinal striae and the more irregular transverse striae, with finer intermediate lines of growth.

UPPER HELDNERBERG GROUP.

Palæontology of NY Vol V Pt II

Plate CXII.

PLATE CXII.—*Continued.*

ORTHOCERAS OPPLETUM.

Page 243.

See Plate 81.

- Fig. 11. An oblique view of two air-chambers, showing the raised areola around the siphuncle, with the furrows at its margin, produced by the solution of the organic deposit, and also the striated surface of the septa. Schoharie grit. Albany county, N. Y.

ORTHOCERAS LUXUM.

Page 244.

See Plates 35, 76, 77, 78, 78 B, 81.

- Fig. 12. A fragment embracing several air-chambers, which have been nearly filled with organic deposit. The greater portion of the specimen shows the pits left by the solution of the material of the deposit, but in the last air-chamber the deposit itself is preserved, as indicated by the small, globular masses filling the cavity of the chamber. Schoharie grit. Albany county, N. Y.
- Fig. 13. A weathered fragment, which preserves the furrowed cylinder around the siphuncle, and the pits, with smaller furrows on the septa, as produced by the organic deposit. Schoharie grit. Schoharie, N. Y.
- Fig. 14. An enlargement of a fragment to two diameters, showing the characters of the organic deposit more in detail than is shown in the preceding illustrations. The cylinder of the elevated areola around the siphuncle, may be traced by the irregular longitudinal furrows, which are a distinguishing feature of the areola, as it becomes more prominent toward the apex of the tube, due to the increase in the amount of the deposit. The small pits formed by the solution of the deposit are continued over the entire interior of the air-chambers, indicating its extent and the nearly complete obliteration of the cavities of the air-chambers. Schoharie grit. Schoharie, N. Y.

ORTHOCERAS PRAVUM.

Page 255.

See Plates 35, 36, 81.

- Fig. 15. Ventral view of two air-chambers, showing the obscuration of the ornamentation on the septa, as represented in fig. 17, by an organic deposit around the margins of the areola and the ovate, lateral expansion, extending over the ventral walls of the air-chambers. On one of the chambers are shown the remains of the concentric striæ surrounding the areolar marking. The organic deposit consists of coarse, globular masses and a finer deposit over the walls of the air-chambers. These features are indicated, as in the specimens of *O. luxum* here illustrated, by the furrows and small pits made in the foreign matter, filling the cavities of the chambers by the solution of the calcareous deposit.
- Fig. 16. The concave side of a septum, showing the lamellose-striate areola around the siphuncle, and its extension to the ventral side. Schoharie grit. Schoharie, N. Y.
- Fig. 17. The convex side of a septum, as shown in a well-preserved fragment. The siphuncle is represented as surrounded by the raised areola, with its lamellose-striate margin and the expansion extending over the septa and along the ventral walls of the air-chambers. This ornamentation of the septa is conspicuously different from that shown in *O. luxum*, and is probably not due to an organic deposit, but to markings made by the mantle of the mollusk. Schoharie grit. Albany county, N. Y.

PLATE CXIII.

BACTRITES CLAVUS.

Page 316.

See Plate 84.

- Fig. 1. Ventral (†) view of an individual, preserving a portion of the chamber of habitation and twenty-five air-chambers, showing the form of the shell, the "dorsal lobe" and the curvature of the sutures. The greater portion of the shell has been filled and replaced by iron pyrites, which has formed an irregular mass at the upper extremity of the chamber of habitation. The apical air-chambers have not been filled with this mineral, and are macerated and disturbed by compression. Marcellus shale. Schoharie, N. Y.
- Fig. 2 *id.* An enlargement of five air-chambers, showing the different aspects of the "dorsal lobe," as produced by the exfoliation of the test. In no case is it a sinus in the septal margins, but is a hiatus in the walls of the internal mould of the air-chambers, from the contact of the siphuncular tube with the inner surface of the test.
- Fig. 3 *id.* Lateral view of three air-chambers, showing the curvature of the sutures over the lateral face of the tube, and the concavity of the septa in a dorso-ventral direction. The tube of the siphuncle is slightly projecting from the lower septum, and the septa are somewhat advanced on this side.
- Fig. 4 *id.* Dorsal view of the same, showing the slight longitudinal carina along the walls of the air-chambers and the concavity of the septa in a lateral direction.
- Fig. 5 *id.* A septum showing the transverse section of the tube, and the size and position of the siphuncle.

ORTHOCERAS SCINTILLA.

Page 293.

See Plate 84.

- Fig. 6. A specimen, natural size, showing the form of the shell and the depth of the air-chambers. From the shales of the Hamilton group. Pratt's Falls, Onondaga county, N. Y.
- Fig. 7. An enlargement of a longitudinal section of three air-chambers, showing the concavity of the septa and the large central siphuncle, without any expansions of its tube or circumposed organic deposit.
- Fig. 8. A similar enlargement of another fragment, showing the expansion of the siphuncular tube, principally at one side.
- Fig. 9. Another fragment in which the siphuncle is equally expanded in the anterior portion of each air-chamber.
- Fig. 10. An enlargement of the lower septum of fig. 7, showing a small concentric areola around the insertion of the siphuncle.
- Fig. 11. A septum corresponding to fig. 8, showing the central position of the siphuncle at its insertion in the septum, and the excentric areola from the asymmetrical expansion of the tube in the cavity of the preceding air-chamber.
- Fig. 12. A septum of specimen fig. 9, with a large central areola around the insertion of the siphuncle, corresponding to the great expansion of the tube in the air-chambers.

ORTHOCERAS CROTALUM.

Page 296.

See Plates 42, 82.

- Fig. 13. The apical portion of a small individual enlarged three diameters, preserving the initial extremity, and showing the umbilical cicatrice at the apex, the ornamentation of the test, and the depth of the air-chambers. The first air-chamber is seen to be much deeper than those succeeding. Hamilton group. Pratt's Falls, N. Y.
- Fig. 13 *a.* The initial extremity of the preceding, further enlarged, to show the characters of the umbilical cicatrice more in detail.

HAMILTON & CHEMUNG GROUPS.

Plate CXIII.

PLATE CXIII—*Continued.*

ORTHOCERAS TEXTUM.

Page 285.

- Fig. 14. An individual showing the form of the shell and the character of the surface-markings, which are preserved over the entire exterior of the tube. Limestone of the age of the Hamilton group. *Falls of the Ohio, near Louisville, Ky.*

ORTHOCERAS TENERE.

Page 285.

- Fig. 15. An individual preserving several air-chambers near the apex, and showing the form of the tube. This specimen and the preceding of *O. textum* have become silicified, and the internal characters of the septa and siphuncle are obliterated. From limestone of the age of the Hamilton group. *Falls of the Ohio, near Louisville, Ky.*

ORTHOCERAS FUSTIS.

Page 281.

See Plate 83.

- Fig. 16. The chamber of habitation entire, with several attached air-chambers. The septate portion is covered with the test and shows the surface characters. The chamber of habitation retains fragments of the test and shows the internal mould, which is marked by a decided constriction of the tube near the aperture, and a more gentle constriction near the base of the chamber. The aperture is entire, and a small fragment of the test presents its natural acute margin. Goniatic limestone. *Schoharie, N. Y.*

- Fig. 17. A septum of the preceding, showing the central position of the siphuncle.

ORTHOCERAS MARCELLENSE.

Page 273.

See Plates 38, 83.

- Fig. 18. A fragment showing the internal mould of the air-chambers and the characters of the organic deposit. The larger extremity preserves three longitudinal carinæ, of which the central one is stronger, and marks the ventral side of the tube. Proceeding in the direction of the apex, the organic deposit is first exhibited as small, irregular masses of calcareous matter, arranged somewhat symmetrically in regard to the ventral line. It increases in amount and complexity, until, at the smaller extremity, the cavities of the air-chambers are nearly filled with the deposit. Goniatic limestone. *Manlius, N. Y.*

ORTHOCERAS COCHLEATUM.

Page 308.

- Fig. 19. An individual nearly entire, showing the form of the tube and the curvature and obliquity of the septal sutures. The chamber of habitation shows a slight constriction of the tube near the aperture, with a contraction at the aperture, and preserves traces of transverse lamellose surface-markings. Upper Chemung group. *Warren, Pa.*

ORTHOCERAS BIPARTITUM.

Page 313.

- Fig. 20. A small fragment preserving a portion of the grand chamber, with ten attached air-chambers, showing the prominent annulations on the chamber of habitation, and their absence over the septate portion. The internal mould preserves traces of sharp longitudinal striae and transverse lines of growth.

PLATE CXIII—*Continued.*

Fig. 21. A fragment of another individual showing nearly the same characters as the preceding. In this example the air-chambers include several annulations, and are much deeper than in the smooth portion of the tube.

The specimens of this species here figured are from the sandstones of the Upper Chemung group, at *Warren, Pa.*

ORTHOCERAS CÆLAMEN.

Page 298.

See Plates 42, 43, 82.

Fig. 22. A fragment preserving portions of the test, and showing the natural form of the tube and characters of the annulations.

Fig. 23. A septum of another individual enlarged two diameters, showing the transverse section of the tube and the position of the siphuncle, with the small raised areola around its insertion, and the radiating vascular markings extending to the margin of the septum. Hamilton group. *Moravia, near Cayuga lake, N. Y.*

ORTHOCERAS LIMA.

Page 303.

Fig. 24. A fragment showing the gradually enlarging tube, and the numerous sharp annulations ornamenting its surface. Hamilton group. *Cazenovia, N. Y.*

Fig. 25. An enlargement of a portion of the surface of the preceding, showing the character of the annulations and the longitudinal striæ, interrupted by the lines of growth between the annulations.
